Head On Interaction Region -Final Focus Optimization-

Jacques PAYET
CEA/DAPNIA/SACM

Small Angle Workshop
2006 October 19th-20th

Outline

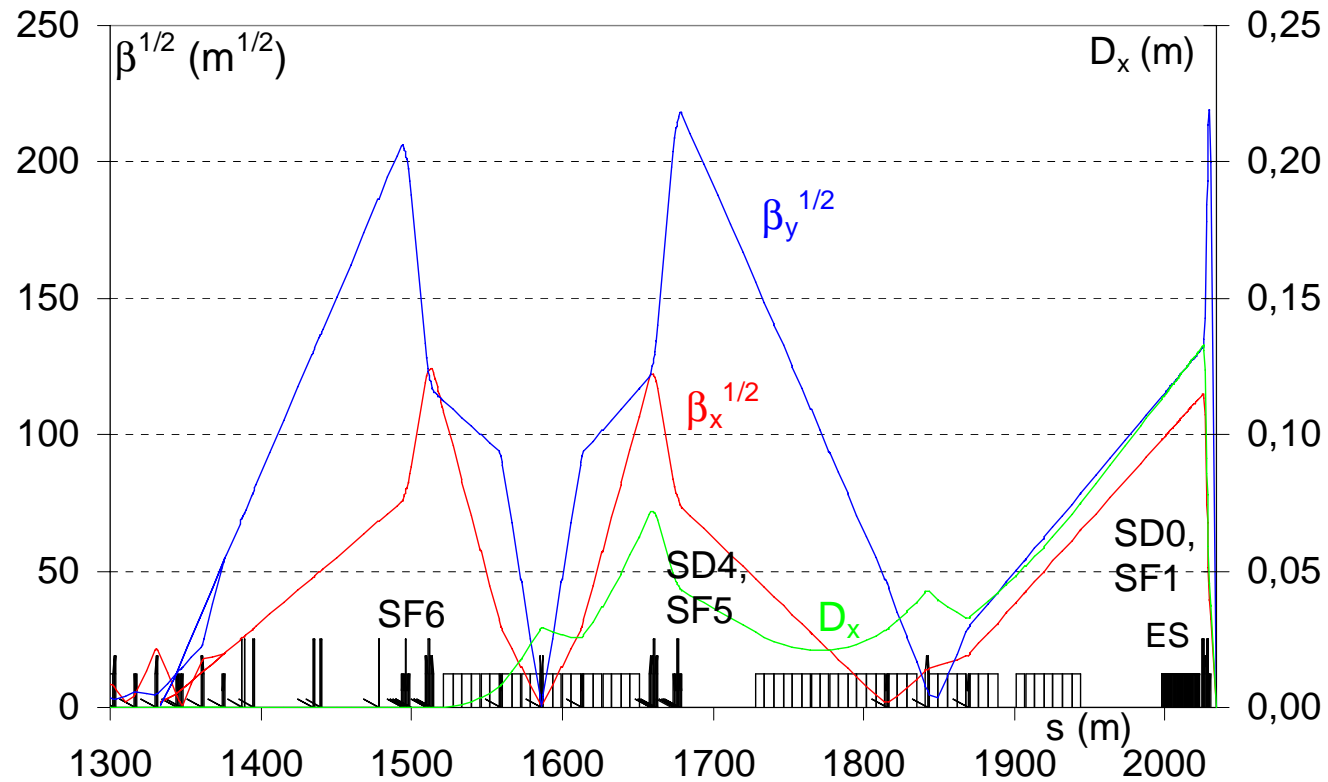

- Final Focus System
- Final Focus Optimization
 - Final Focus Matching
 - Luminosity Optimization
- BDS luminosity(ILC parameter set) vs. Final Focus geometry
- Conclusions

Final Focus System

- FFS length is about 734 m.
- Combine the Final Focalization and the Chromatic Correction functions
- Have to provide an easy spent beam extraction

Final Focus Matching (1)

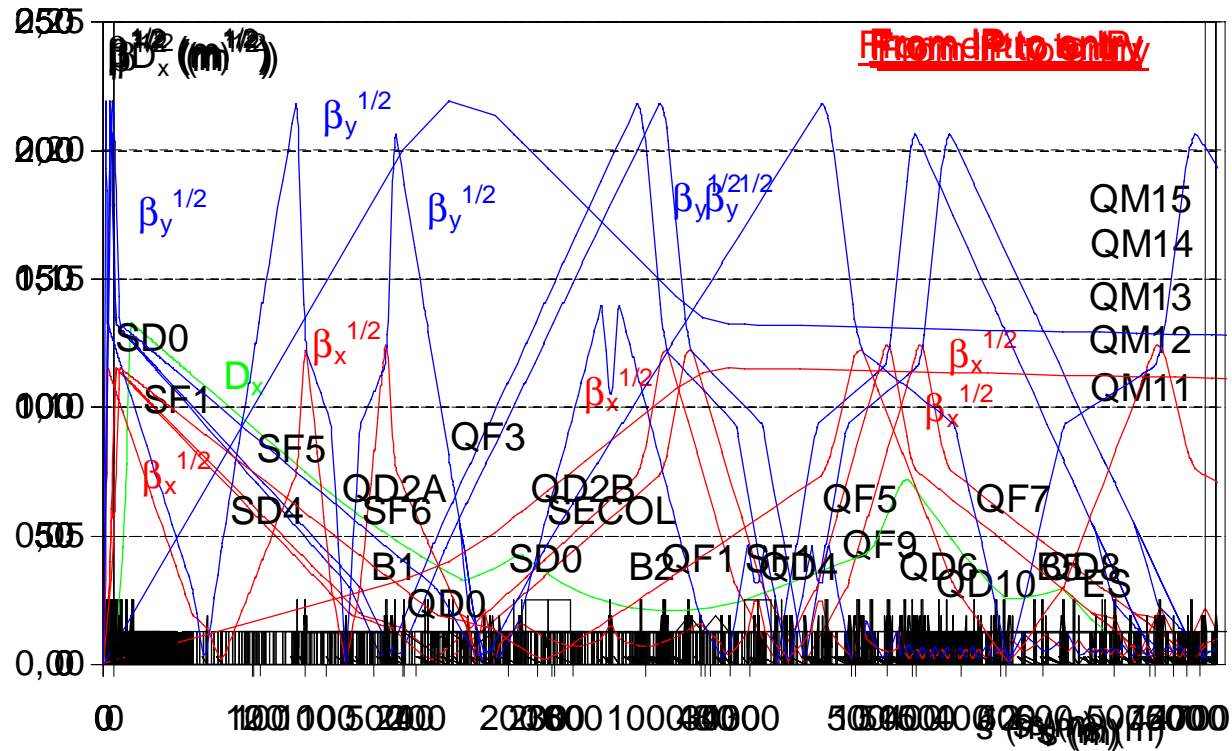

- The Final Focus Matching is performed during 6 stages :
 - From the IP to the FFS entry
 - Matching of the Twiss functions, α_x , α_y , at the FD entry
 - If needed, we change the FD quadrupole length, in order to have the desired gradient, and we repeat the matching
 - Phase advances between paired sextupoles and double waist at QF7
 - Virtual waist near the FFS entry
 - Dispersion and BDS deviation matching
 - We check the B1 field, and if needed, we change α_x and we restart at the 1st step until the B1 field is in the correct range
 - FFS entry Twiss functions matching
 - From the BDS entry to the IP
 - 2nd order terms minimization with the sextupoles
 - If needed, we change the FD sextupole length, in order to have the desired strength, and we repeat the matching
- At the end we have a first FFS tuning and we have to perform a Luminosity Optimization

Final Focus Matching (2) : in pictures

- ~~Estimate the quadrupole strengths and the QF beta deviation~~

Luminosity Optimization (1)

- We use two tools to perform the luminosity optimization :
 - Quick optimization with LUMOPT code (S. Auclair)
 - minimize the beam sizes or maximize the luminosity, at IP
 - the variables are the magnetic elements
 - launch external codes to compute :
 - » the beam sizes : TRANSPORT, MADX-PTC
 - » or the luminosity : DIMAD, LUMTRAK (O.Napoly)
 - different optimization algorithms are available (“classic”, simplex, least square)
 - Final optimization (if needed) with TRACEWIN code (D. Uriot)
 - transport a particle cloud through the beam line and maximize the luminosity at IP by varying the magnetic elements.

cea

saclay

Luminosity Optimization (2) : LUMOPT

- We want to minimize at IP : $\overline{(x_1 - \bar{x}_1)^2 (x_3 - \bar{x}_3)^2}$
- We start with the particle coordinates :

$$x_i = \sum_j R_{ij} x_j^{(0)} + \sum_{jk} T_{ijk} x_j^{(0)} x_k^{(0)} + \sum_{jkl} U_{ijkl} x_j^{(0)} x_k^{(0)} x_l^{(0)} + \sum_{jklm} V_{ijklm} x_j^{(0)} x_k^{(0)} x_l^{(0)} x_m^{(0)} + ..$$

- For the initial beam, we assume that :
 - the odd moments are null : $\overline{x_j^{(0)}} = 0, \overline{x_j^{(0)} x_k^{(0)} x_l^{(0)}} = 0, ..$
 - we can express the high even moments with the 2nd order moments :

$$\overline{x_j^{(0)} x_k^{(0)} x_{j'}^{(0)} x_{k'}^{(0)}} = \overline{x_j^{(0)} x_k^{(0)}} \overline{x_{j'}^{(0)} x_{k'}^{(0)}} + \overline{x_j^{(0)} x_{j'}^{(0)}} \overline{x_k^{(0)} x_{k'}^{(0)}} + \overline{x_j^{(0)} x_{k'}^{(0)}} \overline{x_k^{(0)} x_{j'}^{(0)}}$$

- Then the mean values are :

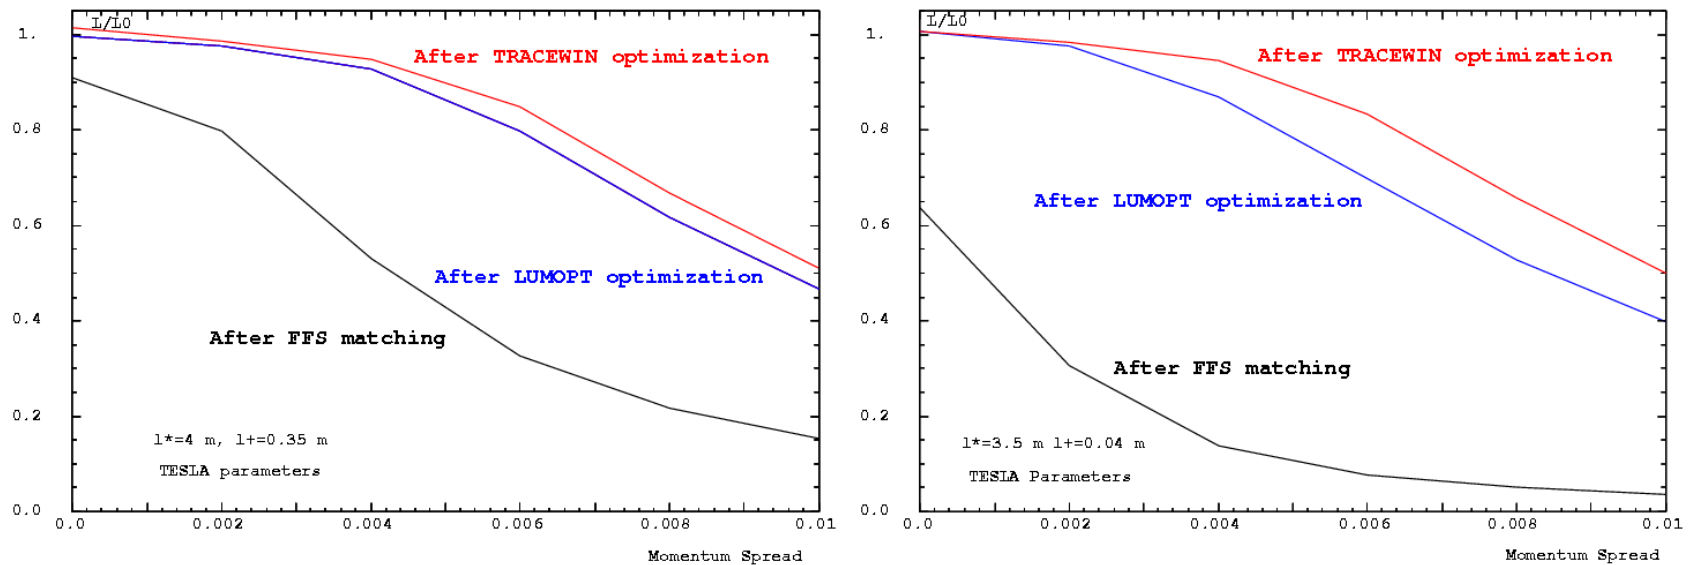

$$\bar{x}_i = \sum_{jk} T_{ijk} \overline{x_j^{(0)} x_k^{(0)}} + \sum_{jklm} V_{ijklm} \overline{x_j^{(0)} x_k^{(0)} x_l^{(0)} x_m^{(0)}} + ..$$

- And the rms values are :

$$\begin{aligned} \overline{(x_i - \bar{x}_i)^2} &= \sum_{jj'} R_{ij} R_{ij'} \overline{x_j^{(0)} x_{j'}^{(0)}} + \sum_{jkj'k'} T_{ijk} T_{ij'k'} (\overline{x_j^{(0)} x_k^{(0)} x_{j'}^{(0)} x_{k'}^{(0)}} - \overline{x_j^{(0)} x_k^{(0)}} \overline{x_{j'}^{(0)} x_{k'}^{(0)}}) \\ &+ 2 \sum_{jklj'} U_{ijkl} R_{ij'} \overline{x_j^{(0)} x_k^{(0)} x_l^{(0)} x_{j'}^{(0)}} + \sum_{jklj'k'l'} U_{ijkl} U_{ij'k'l'} \overline{x_j^{(0)} x_k^{(0)} x_l^{(0)} x_{j'}^{(0)} x_{k'}^{(0)} x_{l'}^{(0)}} \\ &+ 2 \sum_{jklmj'k'} V_{ijklm} T_{ij'k'} (\overline{x_{j'}^{(0)} x_k^{(0)} x_j^{(0)} x_k^{(0)} x_l^{(0)} x_m^{(0)}} - \overline{x_{j'}^{(0)} x_k^{(0)}} \overline{x_j^{(0)} x_k^{(0)} x_l^{(0)} x_m^{(0)}}) + .. \end{aligned}$$

Luminosity Optimization (3) : Luminosity result

BDS Normalized Luminosity v.s Momentum Spread

- LUMOPT gives a good starting point, and some time it is sufficient.
- The TRACEWIN optimization time is decreased (~3 h compare to 1 night)

⇒ To perform a full optimization we need about 1/2 -1 day

BDS Luminosity vs. Final Focus geometry

The goal is to compare the obtained luminosity curves for various parameter sets when we vary $I_{\text{QD-QF}}$ and I^*

Constraints and variables :

- Varying I^*
- Varying $I_{\text{QD-QF}}$ between FD quadripoles
- FD quadripoles with maximum gradient (~ 250 T/m).
- FD sextupoles with maximum strength (~ 3 T at ϕ 56 mm).
⇒ The element lengths are minimum
- 2 m long drift between the last sextupole and the separator.
- B1 deviation is about $2.6 \cdot 10^{-5}$ rad.
- The distance IP→B1 is kept identical.

Parameter Space for $E=250 \text{ GeV } L=2 \cdot 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

BDS : Luminosity

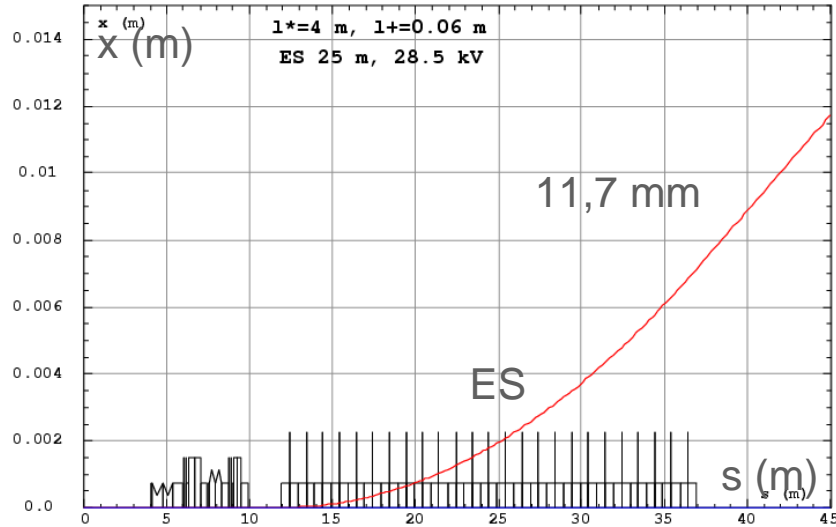

Luminosity vs. Momentum spread

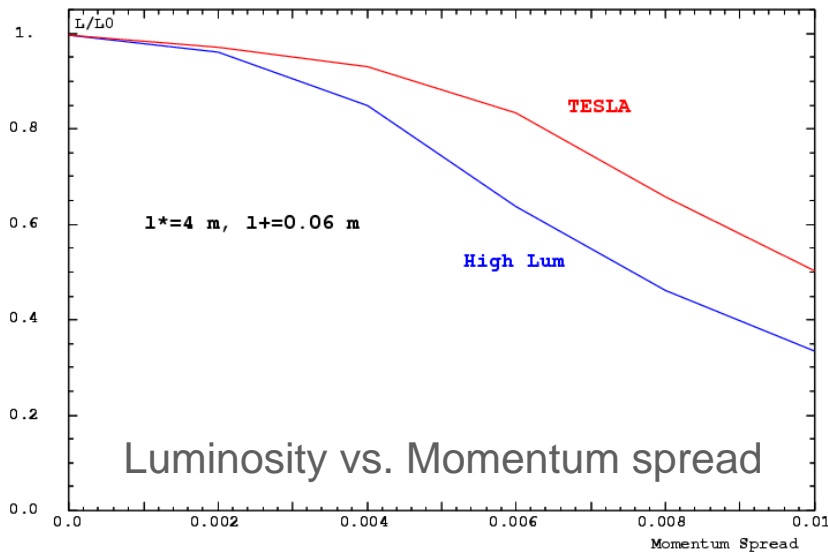

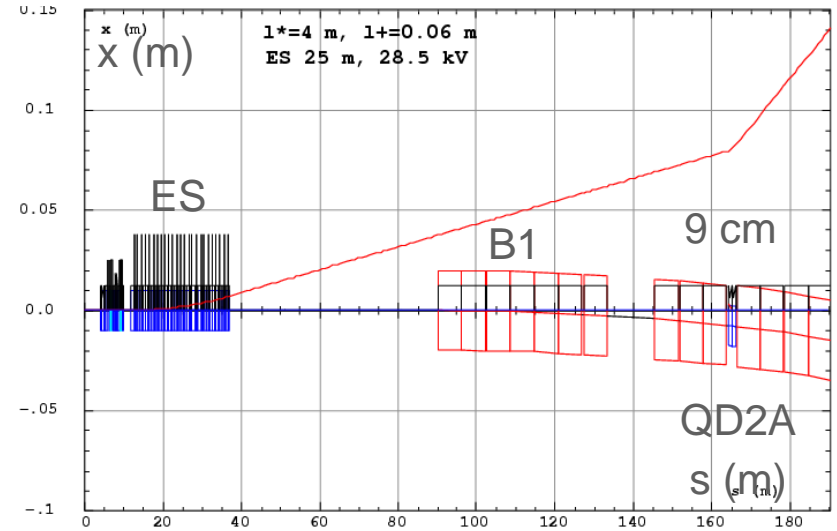

- Full optimization for the TESLA case.
- Matching with QM15-QM11 and luminosity optimization for High Lum. case.
- The “best” luminosity curves are obtained for the largest free drift.
- The luminosity curves are very similar for $l^*=4$ m and $l^*=3.5$ m.

Final Focus with $l^*=4.0$ m

Spent beam at parasitic crossing

Spent beam at QD2A

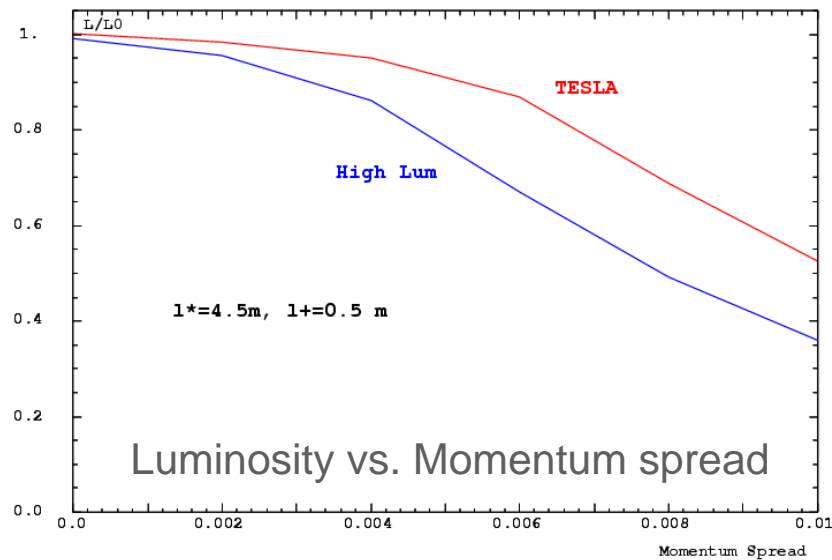

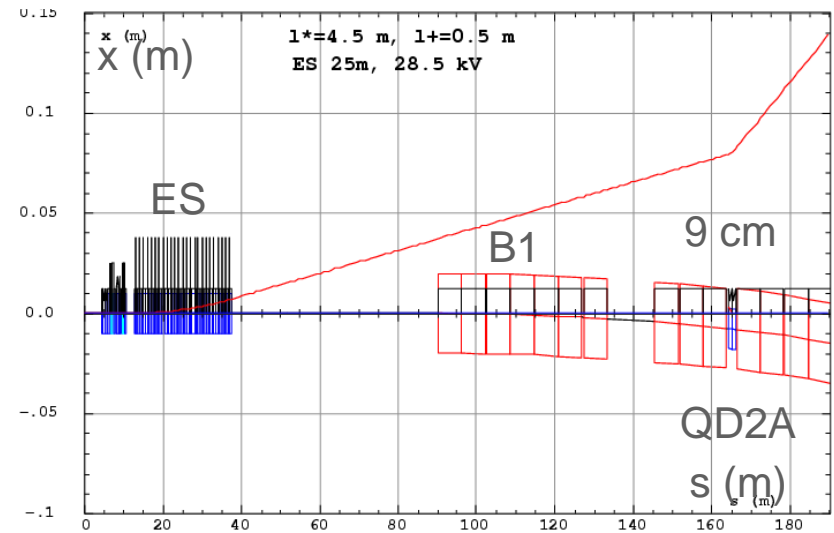

- QD0 + 0.7 m, QF1 + 0.5 m
- SD0 + 0.5 m, SF1 + 0.5 m
- B1 deviation $1.9 \cdot 10^{-5}$ rad
- ES 25 m, 0.00057 rad
- IP \rightarrow ES 11.8834 m

Final Focus with $l^*=4.4$ m

Spent beam at parasitic crossing

Spent beam at QD2A

- QD0 + 0.7 m, QF1 + 0.5 m
- SD0 + 0.5 m, SF1 + 0.5 m
- B1 deviation $1.9 \cdot 10^{-5}$ rad
- ES 25 m, 0.00057 rad
- IP \rightarrow ES 12.3644 m

Conclusions

- The tools for the BDS optimization allow quick optimizations.
- For various Final Focus geometry we have obtained comparable BDS Luminosity curves for two ILC parameter sets.
- The extraction and the experimentation needs are strong guides for the Head On Final Focus geometry :
 - enlarge I^* in order to minimize the solenoid field in QD0.
 - shorten the distance between the IP and the ES to improve the extraction
 - ⇒ maximize the quadripole gradient (250 T/m)
 - ⇒ maximize the sextupole strength (3 T at ϕ 56 mm)
 - ⇒ with a 25 m long 28.5 kV field ES, the beam separation at the parasitic crossing is sufficient to avoid mkink instabilities.
 - decrease the B1 field to keep reasonable QD2A aperture.

| l^* (m) | QD0 (m) | SD0 (m) | QF1 (m) | SF1 (m) | IP To ES (m) |
|-----------|---------|---------|---------|---------|--------------|
| 4.4 | 1.142 | 0.628 | 0.682 | 0.410 | 12.3644 |
| 4 | 1.242 | 0.744 | 0.732 | 0.504 | 11.8834 |

BDS Chromaticities for $l^*=4m$

When the distance decrease :

- The QP chromaticities increase
- The SF1 coupling increase and it counteracts the SD0 contribution
- The SX correction increase

⇒ Are the luminosities similar ?
